Explain how the scientific theory of evolution is supported by the fossil record, comparative anatomy, comparative embryology, biogeography, molecular biology, and observed evolutionary change.

STANDARD REVIEW

In 1859, the English naturalist Charles Darwin published convincing evidence that species evolve, and he proposed a reasonable mechanism explaining how evolution occurs. Darwin proposed that individuals that have physical or behavioral traits that better suit their environment are more likely to survive and will reproduce more successfully than those that do not have such traits. Darwin called this differential rate of reproduction natural selection. In time, the number of individuals that carry favorable characteristics that are also inherited will increase in a population. And thus the nature of the population will change—a process called evolution.

Darwin further suggested that organisms differ from place to place because their habitats present different challenges to, and opportunities for, survival and reproduction. Each species has evolved and has accumulated adaptations in response to its particular environment. An adaptation is an inherited trait that has become common in a population because the trait provides a selective advantage.

Scientists have found many different kinds of evidence that supports the theory of evolution. Fossils offer the most direct evidence that evolution takes place. Evidence of orderly change can be seen when fossils are arranged according to their age. The anatomy and development of living things also shows evidence of evolution. For example, the similarities of structures in different vertebrates provide evidence that all vertebrates share a common ancestor. Biological molecules also show evolutionary relationships. Differences in amino acid sequences and DNA sequences are greater between species that are more distantly related than between species that are more closely related.

STANDARD PRACTICE

- When Darwin first proposed his theory of evolution by natural selection, the field of genetics did not yet exist. In what way does genetic science now contribute to the study of evolution?
 - Scientists can create organisms that were extinct using DNA from fossils and better understand how they evolved.
 - Scientists can use genetic engineering to carry out the process of evolution over just months instead of millions of years.
 - Scientists can compare the DNA from fossils in rock to determine evolutionary relationships among extinct species.
 - Scientists can determine evolutionary relationships among living species by comparing amino acid sequences coded for by DNA.
- Scientists look at evidence to determine possible evolutionary relationships and mechanisms. Which of the following provides strong evidence for evolution?
 - The fossil record
 - Forensic biology
 - Phylogenetic trees
 - Works of philosophy
- The picture to the right show similarities among the forelimbs of three mammals.

Cat's leg Dolphin's flipper Bat's wing

 - Legs and wings may have evolved from flippers.
 - All mammals have evolved from an ancestor that was a bat.
 - A cat's leg, a dolphin's flipper, and a bat's wing have identical functions.
 - Cats, dolphins, and bats may have had the same ancestor millions of years ago.
- How does drug resistance develop in bacteria?
 - Unsanitary conditions allow all kinds of bacteria to breed, including those that are antibiotic resistant.
 - In the blood stream, different species of bacteria exchange genes and become resistant to antibiotics.
 - Mutations in some bacterial genes make the bacteria stronger and better able to defeat the body's immune system.
 - In the presence of an antibiotic, bacteria with genes that make them resistant survive and eventually take over the population.
